Topic Evaluation

As we move forward with various topic modeling approaches, we want to improve the way we evaluate them. Currently, we're manually looking at the documents assigned to each topic. As the number of topics increases, this gets harder to do efficiently. Moreover, a few approaches have hyperparameters, like ε in DBSCAN, and we'll want a more quantitative approach so that the hyperparameters can be tuned.

Approach

This notebook will explore creating a class that accepts a topic modeling function and a testing corpus. The function must take a list of documents (as well as a value for ε, in the case of `k-means`) and then return a list of integer topic assignments, with a value of `-1` for a document if it isn't clustered. The four models used in this notebook all must be initialized and then the `run()` method must be called to train them. In the future, additional models don't necessarily need to have a single `run()` method for training; as long as it has a function that takes a list of documents and returns the topic IDs, it will be compatible.

This notebook will then run the class on a corpus of linked SRs that are linked to a single KB article. The link of the SR will then be used to evaluate the clusters.

Playing around with metrics.homogeneity_score()

`sklearn` has a `homogeneity_score()` function that takes a list of the true labels and a list of the topic IDs and returns the homogeneity score for the model. A value of `1` means that in each topic, all of the documents have the same linked KB. If none of the documents share a linked KB in any topic, the resulting score is `0`. See [homogeneity score (http://scikit-learn.org/stable/modules/generated/sklearn.metrics.homogeneity_score.html#sklearn.metrics.homogeneity_score](http://scikit-learn.org/stable/modules/generated/sklearn.metrics.homogeneity_score.html#sklearn.metrics.homogeneity_score)

```
In [1]:  from sklearn import metrics

         # In this example, there are three topics, each with 2 documents. The tw
         o documents in topic 0 share a true label of 2,
         # while the other two sets of documents do not share the same label.

         labels_pred = [0, 0, 1, 1, 2, 2]
         labels_true = [2, 2, 2, 1, 2, 1]

         metrics.homogeneity_score(labels_true, labels_pred)

Out[1]:  0.27401754212128104
```

In [2]:
```python
# Similar to before but with modified label names to bring it closer to
 our use case.
# Note: the true labels don't need to be integers. Also, their actual va
lues can be changed and the results won't
# be affected as long as they maintain the same order and count.

assigned_topic_ids = [0, 0, 0, 1, 1, 2, 2, 2]
linked_kb_id = ["0", "1", "1", "1", "1", "3", "3", "3"]
print(metrics.homogeneity_score(linked_kb_id, assigned_topic_ids))

modified_linked_kb_id = ["a", "b", "b", "b", "b", "c", "c", "c"]
print(metrics.homogeneity_score(linked_kb_id, assigned_topic_ids))
```

```
0.755014678359733
0.755014678359733
```

Creating a class that will evaluate a given model

The `ModelEvaluation` class can compute certain statistics of a clustering model. When a new instance is created, it must be given the `predict()` method, a list of arguments for `predict()` that at the very least includes test documents (in a format compatible with the `predict()` method. Ex: list of strings for `DBSCAN` or list of vectors for `k-means`) and test corpus (as a list of `Search` objects). Note that the method doesn't necessarily need to be called "`predict`".

When the `ModelEvaluation` object is initialized, the function is called on the test documents in order to obtain the list of topic IDs. The links are also extracted from the test corpus for all of the documents that were assigned to a topic. Finally, the list of topic IDs is modified to remove the `-1` values, which correspond to documents that weren't assigned a cluster.

```
In [318]:  from sklearn import metrics
           import pandas as pd
           class ModelEvaluation:

               # the class takes a function. The function takes a list of documents
            and will return a list of topic assignments
               def __init__(self, model_fn, predict_args, test_searches):
                   self.model_fn = model_fn
                   self.topic_ids = model_fn(*predict_args)
                   self.predict_args = predict_args
                   self.links = [question.link_to_solution[0] for tid, question in
           zip(self.topic_ids, test_searches)
                                                                   if tid != -1]
                   # remove non-assignments from the topic_ids
                   self.topic_ids = [tid for tid in self.topic_ids if tid != -1]

               # homogeneity: each cluster contains only members of a single class.
               def get_homogeneity_score(self):
                   return metrics.homogeneity_score(self.links, self.topic_ids)

Creating a test set

The `NGramClusterer` weights the ngrams based on their frequency within a set of KB articles. Since the evaluation metrics rate the clusters based on the KB articles they're linked to, a train/test split will be used. Moreover, to remain consistent across the different models, just the test set will be used in the evaluation of all models.

```
In [213]: train_fraction = 0.5
```

```

Evaluating `KMeansModeler`

The `predict()` method for the `KMeansModeler` class also takes a value for ε, which is the upper limit for including a document within a topic. The Euclidean distance from the document vector to each topic vector is computed and the document is assigned to the closet topic. Once all of those closest distances are computed, they're normalized by dividing each term by the maximum distance. These normalized distances are then compared to ε, so ε should be in the range `(0, 1]`.

```
In [302]:  %autoreload 2
           from topic_modeling.it_models import KMeansModeler
```

Evaluating `LDATopicModeler`

First, we'll run it for a single LDA model.

```
In [490]: %autoreload 2
          from topic_modeling.it_models import LDATopicModeler
```

In [ ]:
```
lda_modeler = LDATopicModeler(test_corpus, 10, max_features=10000, key=lambda search: search.body)
lda_modeler.run()

ldaEval = ModelEvaluation(lda_modeler.predict, [test_bodies], test_corpus)
```

In [488]:
```
ldaEval.summary().assign(Clustered_docs=len(ldaEval.topic_ids))
```

Out[488]:

	Homogeneity	Completeness	V-measure	Clustered_docs
0	0.292667	0.923419	0.444466	121

Trying different hyperparameters

In [492]:
```python
from itertools import product
ns = [10, 25, 50, 75, 100, 250, 500]
eps = [0.2, 0.30, 0.5, 0.75, 0.8, 0.9]

lda_models = [LDATopicModeler(test_corpus, n, epsilon=eps, max_features=
10000, key=lambda search: search.body)
              for (n, eps) in product(ns, eps)]

for model in lda_models:
    model.run()
```

Plotting the results

The following plot shows the v-measure for each of the models for the different number of clustered docs. In the event that two models have the same number of clustered docs, the maximum v-measure is what's used in the plot.

```python
import matplotlib.pyplot as plt

ax = pd.concat(kmeans_results).sort_values(by="Clustered_docs").groupby
(["Clustered_docs"]).max()["V-measure"].plot(label="Kmeans")
pd.concat(dbscan_results).sort_values(by="Clustered_docs").groupby(["Clu
stered_docs"]).max()["V-measure"].plot(label="DBSCAN")
pd.concat(ngram_results).sort_values(by="Clustered_docs").groupby(["Clus
tered_docs"]).max()["V-measure"].plot(label="NGrams")
pd.concat(lda_results).sort_values(by="Clustered_docs").groupby(["Cluste
red_docs"]).max()["V-measure"].plot(label="LDA")

ax.set_ylabel("V-Measure")
ax.set_title("Topic Modeling Quantitative Results")
handles, labels = ax.get_legend_handles_labels()
ax.legend(handles, labels)
```

Out[524]: <matplotlib.legend.Legend at 0x7f6e7dae2438>

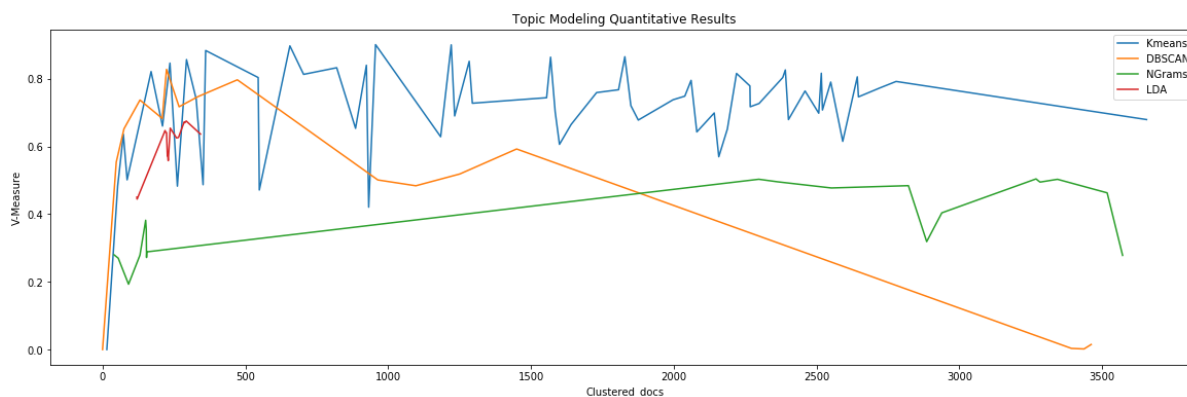

```python
len(test_bodies6_5)
```
